## Inference in Shift-Share Designs

Michal Kolesár 2019-02-06

The package BartikSE implements confidence intervals proposed by Adão, Kolesár, and Morales (2018) for inference in shift-share least squares and instrumental variables regressions, in which the regressor of interest (or the instrument) has a shift-share structure, as in Bartik (1991). A shift-share variable has the structure  $X_i = \sum_{s=1}^{S} w_{is} \mathcal{X}_s$ , where *i* indexes regions, *s* indexes sectors,  $\mathcal{X}_s$  are sectoral shifters (or shocks), and  $w_{is}$  are shares, such as initial share of region *i*'s employment in sector *s*.

This vignette illustrates the use of the package using a dataset from Autor, Dorn, and Hanson (2013) (ADH hereafter). The dataset is included in the package as the list ADH. The first element of the list, ADH\$reg is a data-frame with regional variables, the second element, ADH\$sic is a vector of SIC codes for the sectors, and ADH\$W is a matrix of shares. See ?ADH for a description of the dataset.

We now replicate the first row of Table 6 in Adão, Kolesár, and Morales (2018). First we load the package, define the vector of controls, and define a vector of 3-digit SIC codes:

We cluster the standard errors at the 3-digit SIC code (using the option sector\_cvar), and, following ADH, weight the data using the weights ADH\$reg\$weights. See ?lmBartik and ?IVBartik for full description of the options.

The first-stage regression:

```
lmBartik(as.formula(paste("shock ~ ", ctrls)), W = ADH$W,
   X = IV, data = ADH$reg, weights = weights, region_cvar = statefip,
    sector_cvar = sic, method = "all")
#> Estimate: 0.6310409
#>
#> Inference:
                                 p-value Lower CI Upper CI
#>
                 Std. Error
#> Homoscedastic 0.02732516 0.000000e+00 0.5774846 0.6845973
                 0.08700719 4.083400e-13 0.4605100 0.8015719
#> Req. cluster 0.09142372 5.113909e-12 0.4518537 0.8102281
#> AKM
                 0.05296055 0.000000e+00 0.5272402 0.7348417
#> AKMO
                 0.07671358 1.282891e-03 0.5375710 0.8382827
```

Note that for AKM0, "Std. Error" corresponds to the normalized standard error, given by the length of the confidence interval divided by  $2z_{1-\alpha/2}$ 

The reduced-form and IV regressions:

```
lmBartik(as.formula(paste("d_sh_empl ~", ctrls)), W = ADH$W,
    X = IV, data = ADH$reg, region_cvar = statefip, weights = weights,
    sector_cvar = sic, method = "all")
#> Estimate: -0.4885687
#>
#> Inference:
#> Std. Error    p-value    Lower CI    Upper CI
#> Homoscedastic    0.06332778    1.221245e-14    -0.6126889    -0.3644485
```

```
0.11244360 1.392685e-05 -0.7089541 -0.2681833
                 0.07578147 1.140306e-10 -0.6370977 -0.3400398
#> Reg. cluster
